LABORATORY ACTIVITY #4
ASCII Symbol Visualizer

Design and implement a Python program that prompts the user to input a **sentence** and a **display symbol** (a single character). The program will analyze the sentence character by character, calculate a unique numeric value for each character based on its **ASCII value**, and print a horizontal bar of repeating symbols matching that calculated value.

Requirements:

1. **Inputs**: A text string (sentence) and a single-character string (symbol).
2. **Modulo Formula**: Convert each character to its ASCII value and apply **modulo 15** (ascii_value % 15) to determine the symbol count.
3. **Zero Boundary Handling**: If the modulo operation results in 0, the count must automatically scale up to **15** to ensure every character displays at least some symbols.

Sample Output

```
Enter a sentence: hello
Enter the symbol or character to display: *

--- Output ---
'h' (Count: 14) -> **************
'e' (Count: 11) -> ***********
'l' (Count:  3) -> ***
'l' (Count:  3) -> ***
'o' (Count:  6) -> ******
```

Result:

```python
sentence = input("Enter a sentence: ")
symbol = input("Enter the symbol or character to display: ")

print("\n--- Output ---")

for char in sentence:
    ascii_value = ord(char)
    count = ascii_value % 15

    if count == 0:
        count = 15

    bar = symbol * count
    print(f"'{char}' (Count: {count}) -> {bar}")

```

Sample output of that:
